Area Agronomist

The production of animal wastes and their subsequent use as fertilizers and soil amendments will increase as confined poultry and livestock producers expand their market in the meat industry. Animal waste products contain valuable nutrients that are required by forage crops. These nutrients, primarily nitrogen (N), phosphorus (P), and potassium (K), can accumulate on sites with continued application. Forages managed as hay crops can be utilized to remove these nutrients via plant uptake from sites that regularly receive poultry litter, swine lagoon effluent, dairy, and feedlot manure applications. This OSU Extension Fact Sheet discusses the use of forages for nutrient removal from areas subject to manure applications.

Manure Nutrients

Both the poultry and swine industries are presently experiencing dramatic growth in Oklahoma. At present, the poultry production areas in Oklahoma are located primarily in the eastern part of the state, while swine production areas are found in both the eastern and western regions. As the livestock industries have grown, so have the by-products of these production systems. Poultry litter produced is estimated to be 300,000 tons annually in Oklahoma, equivalent in nutrient value to 13,185 tons of 46-0-0, 16,304 tons of 18-46-0, and 9,677 tons of 0-0-62 fertilizers.

Poultry litter is made up largely of poultry manure and bedding materials such as sawdust, wood chips, or rice hulls. The nutrient composition of poultry litter is highly variable, but the average analysis for N-P₂O₅-K₂O per ton of litter is approximately 60-60-50 (Table 1). Poultry litter is generally applied to pastures, either on-farm or within a short distance of the poultry operation. Typical application rates may approach 5 tons of litter per acre per year. Nutrient accumulation or **loading** of elements such as P can occur in a few years, even on P-deficient soils, under these application scenarios. In fact, some fields already have a soil test P (STP) index over 400, and P application from animal manure is no longer permitted in Oklahoma.

Oklahoma Cooperative Extension Fact Sheets

Table 1. Arrange nutrient composition of litter from over 300 samples in Delaware County.

	<i>Dry wt. Basis</i> (%)	<i>As is basis</i> (lbs./ton)	<i>Range</i> (as is)
Moisture (%)	-	25	8.5-65
Nitrogen (N)	3.7	57	14-95
Phosphorus (P ₂ O ₅)	4.1	61	11-108
Potassium (K ₂ O)	3.2	48	15-74
Calcium (Ca)	5.0	70	26-203
pH	7.2	-	5.8-8.8

Use of swine lagoon effluent may cause nutrients to accumulate on a site in a similar manner. Analyses for lagoon effluent are usually given in the pounds of nutrients per 1,000 gallons. The ratio of total N to P₂O₅ to K₂O for swine lagoon effluent generally falls into the ratio of 4-1-5. Actual nutrient concentrations depend on the amount of flushwater added to the lagoon, the amount of precipitation falling on the lagoon, and the level of treatment achieved by the lagoon. Using a typical analysis of 4 lbs. N, 1 lb. P₂O₅, and 5 lbs. K₂O per 1,000 gallons indicates that 1 acre-inch of irrigation yields approximately 108 lbs. N, 27 lbs. P₂O₅, and 135 lbs. K₂O per acre. The amount of plant available N is generally lower than the total N applied due to ammonia (NH₃) volatilization during application.

Management Strategies

Animal manure applications should be managed to prevent excess nutrient loading of sites from repeated applications. The preferred management strategy is to **not** apply more nutrients than can be effectively used by the forage system. Under most circumstances the critical nutrient to monitor will be P. Phosphorus is required in lower quantities by forage plants than either N or K; thus, P is removed in the least quantity by the forage system. If possible, animal manure should only be applied to meet the P requirement of the forage system. Additional N or K should be applied as commercial fertilizer.

If animal manure is applied to meet the N requirement of the forage crop, excess P will accumulate. A long-term research experiment conducted at the OSU Agricultural Experiment Station at Lahoma documents the effect of soil-P depletion and enrichment from 27 years of annually applying 0 to 80 lbs./acre fertilizer P for winter wheat production. The soil test P index is well correlated with net P input (P applied minus P removed). About 14 lbs. P₂O₅/acre is required to raise or lower the soil test P by 1.0 unit for this silt loam soil. Generally, it requires 10 to 20 lbs. P₂O₅/acre to raise soil test P by 1 for a wide variety of soils. For example, soil test P would increase by 12 to 24 per year if 4 tons of litter were applied annually. Routine analyses of animal manure will provide information regarding the level of nutrient inputs the system is receiving. An annual soil test of the application site will indicate the soil phosphorus status and whether an accumulation is taking place.

An important management strategy on sites where nutrient loading is an existing or potential problem is to use a forage crop(s) that removes a maximum level of nutrients, especially the nutrients of concern. Following are a couple of ways to accomplish this.

The first method involves using a forage crop that has a high dry matter yield potential. As dry matter yield increases, the amount of nutrients taken up by the crop increases, and thus, more nutrients can be removed. Bermudagrass is an example of a forage crop that has a high yield characteristic. When grown in eastern Oklahoma with adequate precipitation, or under irrigation elsewhere in the state, bermudagrass is one of the most productive forage grasses for use in a forage system designed for nutrient removal.

Another forage-use strategy involves using forages that have higher nutrient uptake for specific nutrients even though dry matter yield may be less than some other forage crops. Table 2 shows differences between forage species in percentage concentrations of various nutrients contained in plant tissue. Orchardgrass, for example, does not yield as much dry matter as bermudagrass, but its uptake of P is almost twice that of bermudagrass. Concentrations of nutrients in different species can vary depending on plant available nutrients in the soil, yield, and maturity of the forage when cut.

Table 2. Dry matter mineral nutrient composition (%) of selected hays¹.

<i>Species</i>	<i>N</i>	<i>P₂O₅</i>	<i>K₂O</i>	<i>Ca</i>	<i>Mg</i>
Alfalfa	3.2	0.80	2.64	1.80	0.26
Annual ryegrass	3.4	0.78	3.36	0.65	0.35
Bermudagrass	2.5	0.64	2.16	0.37	0.15
Orchardgrass	2.9	1.24	4.30	0.58	0.31
Pearlmillet	2.0	0.40	2.40	-	-
Red clover	2.6	0.57	1.94	1.53	0.43
Smooth bromegrass	3.4	1.03	3.84	0.55	0.32
Sorghum/ sudangrass	1.6	0.41	2.16	0.48	0.30
Tall fescue	2.3	0.85	2.40	0.51	0.19
White clover	3.5	0.71	3.14	1.35	0.48

¹ From Brown, 1996, Robinson, 1996 and NRCS Animal Waste Management Field Handbook.

Alfalfa has both a high yield potential, if given adequate moisture, and a higher P and K requirement than that of bermudagrass. Although a legume is not dependent on applied N, alfalfa receiving N, P, and K as swine lagoon effluent has the potential to remove a large quantity of applied nutrients.

The most efficient nutrient removal forage system will use a combination of both warm- and cool-season forage species to enhance nutrient removal on a year-round basis. A good combination in the eastern third of Oklahoma is tall fescue, a cool-season perennial, with bermudagrass, a warm-season perennial. Farther west, where tall fescue is not adapted, a good combination would be bermudagrass overseeded with a cereal grain such as wheat or rye and ryegrass. Tall fescue pastures could be overseeded with a warm-season annual grass such as crabgrass for summer growth. Likewise, the use of orchardgrass, bromegrass, or wheatgrass (tall or intermediate) with crabgrass would be a good choice for use under irrigation in the western portion of the state.

Warm- and cool-season annuals could also be used for high levels of nutrient removal. Possible species combinations could include double cropping cereal grains with sudangrass, forage sorghums, or pearl millet under irrigation. They can produce large quantities of dry matter and remove high levels of nutrients from sites receiving swine lagoon effluent applications. The negative effects of nitrate accumulation associated with the use of these warm-season annual grasses during times of drought stress would be reduced or eliminated since adequate moisture should be available under irrigation.

It should be noted that nutrients are not effectively removed from the forage system by grazing livestock. Table 3 compares the various levels of nutrient removal by grazing or by haying warm- or cool-season perennial grasses.

Nutrient removal is accomplished only by removing forage as a **hay crop** and transporting the nutrients away from the application site. Grazing, for the most part, recycles most of the nutrients back into the forage system. Continued use of poultry litter or swine lagoon effluent under grazed-only systems will lead to increased nutrient accumulation at that site.

Table 3. Approximate quantities of nutrients removed under grazing and haying systems.

<i>System</i>	<i>Nutrient Removal (lbs./ac)</i>				
	<i>N</i>	<i>P₂O₅</i>	<i>K₂O</i>	<i>Ca</i>	<i>Mg</i>
Grazing ¹	12.5	7.8	0.9	6.5	0.75
Bermudagrass hay ²	250	64	216	79	39
Orchardgrass hay ³	174	73	258	35	19

¹ Assumes 1-500 lb. calf weaned off of 1 acre on a year-round basis. If more than 1 acre per year is required to produce the calf, the values would be reduced.

² Assumes 5-ton yield with all forage removed as hay crop.

³ Assumes 3-ton yield with all forage removed as hay crop.

Efficiency of Nutrient Removal Using Forage

Some fields have already built up high P levels in the soil due to continuous poultry litter application. New regulations set a soil test P limit for additional litter application. For example, under current Natural Resource Conservation Service nutrient management guidelines, no animal manure can be land applied if soil test P is over 400 in Oklahoma. Therefore, some efforts have been made to reduce P in those fields with high yielding forage crops and/or legumes. However, it may take a long time to see a significant soil phosphorus reduction. Figure 1 illustrates the time needed to reduce soil test P by 100 at different forage yields. It takes about 22 years to reduce soil test P by 100 if 5 tons of bermudagrass is removed from the field every year. Therefore, it is a slow process to use forages for lowering the soil phosphorus level.

Figure 1. Number of years needed to decrease Soil Test P (STP) by 100 units with different amounts of forage harvested annually.

Summary

Animal manure contains valuable nutrients and organic matter that can and should be used as a source of plant nutrients and soil amendments in forage production systems. However, continued applications of critical nutrients such as P, in excess of the level that can be effectively removed by the forage system as a hay crop can lead to an accumulation of nutrients. Additionally, on sandy sites, relatively mobile nutrients, such as N, can be leached through the soil profile into groundwater in the underlying aquifers, thus posing a potential environmental hazard.

Forages with a high yield potential can be used effectively to remove nutrients from application sites, if application rates are kept within reasonable extents. Bermudagrass and certain warm-season annual grasses have the potential to produce large dry matter yields and thus remove large quantities of applied nutrients. Cool-season grasses and certain legumes have a higher uptake of certain nutrients (such as P) and may remove more specific nutrients than higher yielding forage species, although the yield potential is not as high. Producers should seek to use a combination of both warm- and cool-season forages in a production system that attempts to remove a maximum level of nutrients from sites that regularly receive poultry litter or types of animal manure applications. However, it is a slow process to use forages for lowering the soil phosphorus level. Grazed-only systems will not effectively remove nutrients from an application site since most of the applied nutrients, especially P and K, are recycled to the land during the grazing process.

The Oklahoma Cooperative Extension Service

Bringing the University to You!

The Cooperative Extension Service is the largest, most successful informal educational organization in the world. It is a nationwide system funded and guided by a partnership of federal, state, and local governments that delivers information to help people help themselves through the land-grant university system.

Extension carries out programs in the broad categories of agriculture, natural resources and environment; family and consumer sciences; 4-H and other youth; and community resource development. Extension staff members live and work among the people they serve to help stimulate and educate Americans to plan ahead and cope with their problems.

Some characteristics of the Cooperative Extension system are:

- The federal, state, and local governments cooperatively share in its financial support and program direction.
- It is administered by the land-grant university as designated by the state legislature through an Extension director.
- Extension programs are nonpolitical, objective, and research-based information.
- It provides practical, problem-oriented education for people of all ages. It is designated to take the knowledge of the university to those persons who do not or cannot participate in the formal classroom instruction of the university.
- It utilizes research from university, government, and other sources to help people make their own decisions.
- More than a million volunteers help multiply the impact of the Extension professional staff.
- It dispenses no funds to the public.
- It is not a regulatory agency, but it does inform people of regulations and of their options in meeting them.
- Local programs are developed and carried out in full recognition of national problems and goals.
- The Extension staff educates people through personal contacts, meetings, demonstrations, and the mass media.
- Extension has the built-in flexibility to adjust its programs and subject matter to meet new needs. Activities shift from year to year as citizen groups and Extension workers close to the problems advise changes.

Oklahoma State University, in compliance with Title VI and VII of the Civil Rights Act of 1964, Executive Order 11246 as amended, Title IX of the Education Amendments of 1972, Americans with Disabilities Act of 1990, and other federal laws and regulations, does not discriminate on the basis of race, color, national origin, sex, age, religion, disability, or status as a veteran in any of its policies, practices or procedures. This includes but is not limited to admissions, employment, financial aid, and educational services.

Issued in furtherance of Cooperative Extension work, acts of May 8 and June 30, 1914, in cooperation with the U.S. Department of Agriculture, Samuel E. Curl, Director of Cooperative Extension Service, Oklahoma State University, Stillwater, Oklahoma. This publication is printed and issued by Oklahoma State University as authorized by the Dean of the Division of Agricultural Sciences and Natural Resources and has been prepared and distributed at a cost of 20 cents per copy. 0702
